

1. Access, Roles and Sign-In

This condensed manual covers the complete ICCTECH examination workflow for end users, IT support analysts, system administrators and the examiner. It focuses on authentication, ticket handling, role-based access, knowledge, assets and evaluation support.

Table 1. Access information

Purpose	Address / Source
Live application	http://45.79.223.146:8080/index.php
Staff / analyst / administrator sign-in	http://45.79.223.146:8080/login
End-user self-service sign-in	http://45.79.223.146:8080/self-service/login.php
Source repository	https://github.com/Clemzy123/ICCTECH
Credentials	Use the accounts listed in Deployment_and_Source_Links.txt supplied with the examination package.

Security note. Do not place examiner passwords or production credentials in the public GitHub repository. The submission package contains the credentials separately in Deployment_and_Source_Links.txt.

Examiner uses supplied test/admin credentials to verify the deployed workflow.

Figure 1. ICCTECH user roles and access portals

Role responsibilities

End User: submit, track and reply to tickets and use published knowledge. **IT Support Analyst:** triage, categorise, prioritise, assign, investigate, update, resolve and reopen tickets. **System Administrator:** manage users, roles, permissions and essential configuration under least privilege.

2. Getting Started and End-User Self-Service

Figure 2. Staff and end-user sign-in paths

Sign-in and sign-out

Staff/analyst/administrator: open /login, enter the supplied username and password, then provide the MFA verification code when enabled. End user: open /self-service/login.php, enter the configured email/user identifier and password, and complete MFA when prompted. Always sign out on shared devices.

Optional first: search Knowledge / Help Centre before opening a new ticket.

Figure 3. End-user support-ticket process

End-user ticket procedure

1. Select New Ticket and enter a clear subject and description.
2. Select the relevant queue/category and priority; attach useful evidence when required.
3. Submit and retain the generated ticket reference.
4. Open Your Tickets to review status, priority, ownership and history.
5. Reply through the ticket record when more information is requested.
6. Search Knowledge / Help Centre before or during ticket handling when appropriate.

3. IT Support Analyst Workflow

Figure 4. Analyst triage sequence

Triage, priority and communication

Open the incoming ticket, review the subject/description/attachments, confirm the category or queue, set High/Normal/Low priority according to impact and urgency, assign the appropriate analyst or team, and record investigation notes or requester-facing responses in the ticket history.

Table 2. Typical ticket status meanings

Typical status	Meaning
Open / Awaiting Triage	Ticket has been received and requires review.
Assigned	Ownership has been established.
In Progress	An analyst is actively investigating or working on the request.
On Hold / Awaiting Response	Further action depends on information, an external dependency or the requester.
Resolved	A solution has been recorded and the issue is considered fixed.
Closed	The support process is complete.

Figure 5. Typical ticket status lifecycle

4. Administration, Knowledge and Asset Management

After changing roles or permissions, verify the result using a test account.

Figure 6. Role-based access and least privilege

Administrator controls

Use the Administration/System area to create or update users/analysts, assign roles/teams/capabilities and verify access using an appropriate test account. Grant only the minimum permissions required. Use unique passwords, enable MFA where configured, disable unused test accounts and review privileges periodically.

Knowledge Base

Search the Help Centre / Knowledge area using relevant keywords, open authorised articles and follow documented troubleshooting. Authorised knowledge managers may maintain content according to their assigned capabilities. If self-service does not resolve the issue, create or continue a support ticket.

Only authorised staff should modify ownership, status or custody information.

Figure 7. Asset view, update and assignment flow

Asset procedure

Locate the asset record, review identifying and operational information, update only authorised fields, and use Assign to link the asset to a user (including a return date where required). Verify that the saved value or assigned user is displayed correctly.

5. End-to-End Workflow and Examiner Verification

Recommended quick demonstration of the examination scope.

Figure 8. Core end-to-end demonstration workflow

Figure 9. Examiner quick-verification sequence

Verification outcome

The sequence above verifies site reachability, end-user ticket creation, analyst triage/assignment/communication, requester visibility, resolution/closure, Knowledge and Asset access, and denial of a restricted administrative action to an account without the required capability.

6. Troubleshooting, Security and Responsible Use

Table 3. Troubleshooting

Problem	Recommended action
Live page does not open	Confirm the URL and internet connection. Retry after a short period. If the application remains unavailable, verify Linode/server and Docker service status.
Login rejected	Check the username/email and password in Deployment_and_Source_Links.txt. Confirm the correct portal is being used. Do not repeatedly guess passwords.
MFA prompt appears	Enter the current verification code for the configured account. If the examiner account was not intended to use MFA, use the supplied alternative test account.
A module is missing	Module visibility is role-based. Confirm that the signed-in account has permission for that module.
Cannot perform an administrative action	The account may not have the required capability. Verify the assigned role rather than attempting to bypass access controls.
Ticket update does not appear	Refresh/reopen the ticket and confirm that the save/send operation succeeded. Check for an error message before retrying.
Database-related error	Confirm MySQL service availability and application database connectivity. Production database access should remain restricted to authorised administrators.
Uploaded file fails	Confirm that the file type/size is accepted by the application and that storage permissions are available.
Slow response	Retry the page and confirm server/network conditions. Persistent performance problems should be recorded for maintenance investigation.

During evaluation

If a problem occurs during grading, record the exact page, action performed, time, visible error message and account role. This helps distinguish a user-access issue from an application, database or hosting issue.

Security and responsible use

Use only the accounts and permissions supplied for evaluation. Do not publish credentials, reuse database/server credentials as application passwords, bypass role controls or expose database/server secrets. Sign out after testing on shared devices and avoid entering unnecessary sensitive information into demonstration records. The current examination deployment uses HTTP; HTTPS, stronger secret management, database hardening, backups and monitoring remain production-hardening items documented in the Technical Debt Plan.
